Honest CIs for Average Treatment Effects: NSW Example

Michal Kolesár

Contents

The package `ATEHonest` implements honest confidence intervals and estimators for estimating average treatment effects under unconfoundedness from Armstrong and Kolesár [2017]. Here we illustrate the use of the package using NSW data from Dehejia and Wahba [1999].

The data is shipped with the package, as two data frames, `NSW` (where the treated units are from the experimental sample and control units are from PSID), and `NSWexper`, where both treated and control units are from the experimental sample. We'll use the experimental sample here.

First we extract the design matrix, and the treatment and outcome vectors, and we construct a nearest neighbor estimate of the variance of the regression errors using Mahalanobis distance:

```r
library("ATEHonest")
X <- as.matrix(NSWexper[, 2:10])
d <- NSWexper$treated
y <- NSWexper$re78
DMvar <- distMat(X, chol(solve(cov(X))), method = "euclidean")
sigma2 <- nnvar(DMvar, d, y, J = 3)
```

Next, we compute matrix of distances between treated and control units, using the same weight matrix to compute distances as in Armstrong and Kolesár [2017]:

```r
Ahalf <- diag(c(0.15, 0.6, 2.5, 2.5, 2.5, 0.5, 0.5, 0.1,
    0.1))
D0 <- distMat(X, Ahalf, method = "manhattan", d)
```

We now compute the first couple of hundred steps of the solution path. 200 will be sufficient for computing the optimal estimator. Given the solution path, we then compute the root mean squared error optimal esitmator, as well as estimator that's optimal for constructing tow-sided CIs:

```
res <- ATTh(D0, maxiter = 300)$res
op <- ATTOptPath(res, y, d)
ATTOptEstimate(op, mean(sigma2), C = 1, sigma2final = sigma2,
    opt.criterion = "RMSE")
#>
#>
#> Estimate    Max. bias   SE          CI                        delta
#> ---------   ----------  ----------  ----------------------    ---------
#> 1.589215    1.185809    0.7555214   (-0.8393216, 4.017752)    1.223155
ATTOptEstimate(op, mean(sigma2), C = 1, sigma2final = sigma2,
    opt.criterion = "FLCI")
#>
#>
#> Estimate    Max. bias   SE          CI                        delta
#> ---------   ----------  ----------  ---------------------     ---------
#> 1.62288     1.235031    0.7140335   (-0.786633, 4.032392)     3.289784
```

Efficiency of one- and two-sided CIs at smooth functions (see Appendix A in Armstrong and Kolesár [2017]) is:

```
ATTEffBounds(res, d, mean(sigma2), C = 1)
#> $onesided
#> [1] 0.9917669
#>
#> $twosided
#> [1] 0.9750316
```

For comparison, we also consider matching estimators. First, a matching estimator with a single match:

```
ATTMatchEstimate(ATTMatchPath(y, d, D0, M = 1, tol = 1e-12),
    mean(sigma2), C = 1, sigma2final = sigma2)
#>
#>
#> Estimate    Max. bias   SE          CI                        M
#> ---------   ----------  ----------  ---------------------     ---
#> 1.972065    1.169562    0.7763488   (-0.4744891,  4.41862)    1
```

Next, we optimize the number of matches. For that we first compute the matching estimator for a vector of matches M, and then optimize the number of matches using ATTMatchEstmate:

```
mp <- ATTMatchPath(y, d, D0, M = 1:10, tol = 1e-12)
ATTMatchEstimate(mp, mean(sigma2), C = 1, sigma2final = sigma2,
    opt.criterion = "FLCI")
#>
#>
#> Estimate    Max. bias   SE          CI                      M
#> ---------   ----------  ----------  ----------------------  ---
#> 1.972065    1.169562    0.7763488   (-0.4744891,  4.41862)   1
ATTMatchEstimate(mp, mean(sigma2), C = 1, sigma2final = sigma2,
    opt.criterion = "RMSE")
#>
#>
#> Estimate    Max. bias   SE          CI                      M
#> ---------   ----------  ----------  ----------------------  ---
#> 1.972065    1.169562    0.7763488   (-0.4744891,  4.41862)   1
```

We can see that a single match is in fact optimal for both estimation and construction of two-sided CIs.
